

Combinatorial Fourier transform for type A quiver representation varieties

Pramod N. Achar, Maitreyee Kulkarni, and Jacob P. Matherne

Louisiana State University, University of Massachusetts Amherst

Goal

Give a combinatorial description of the Fourier–Sato transform:

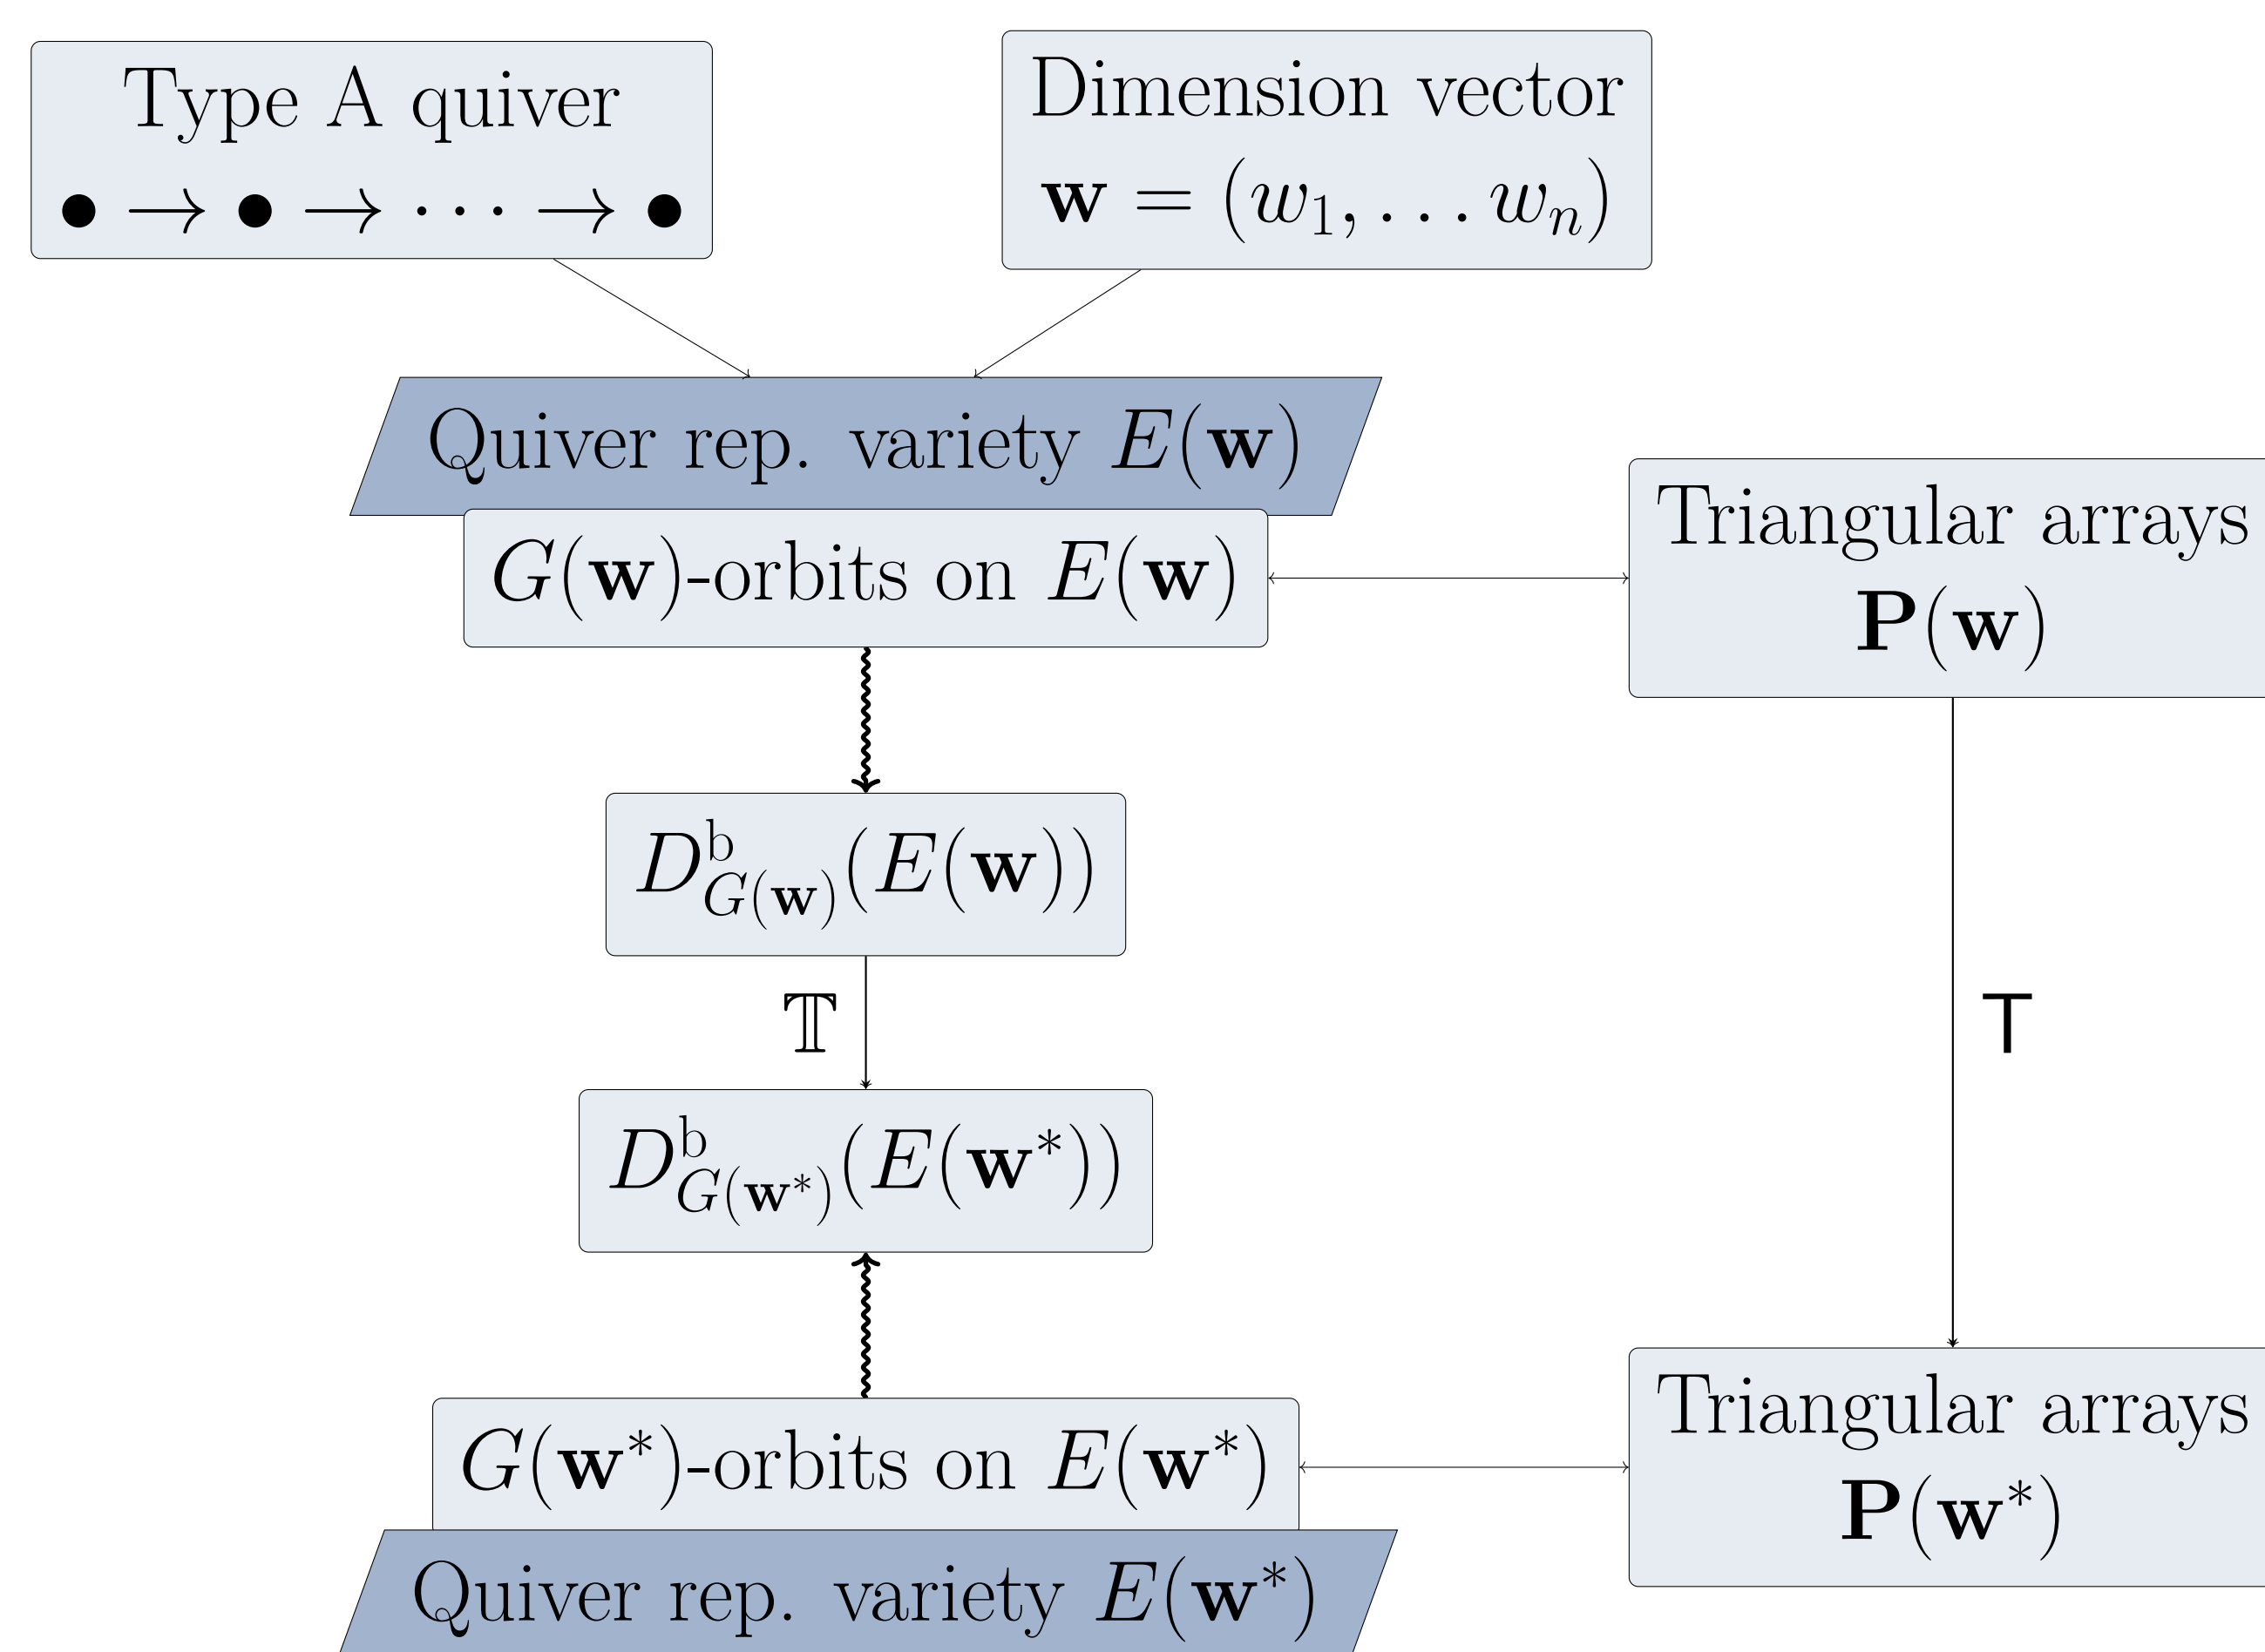

$$D_{G(\mathbf{w})}^b(E(\mathbf{w})) \xrightarrow{\mathbb{T}} D_{G(\mathbf{w}^*)}^b(E(\mathbf{w}^*))$$

$$\mathcal{F} \mapsto q_2! q_1^*(\mathcal{F})[\dim E(\mathbf{w})]$$

where

Overview

Quiver representations

A **quiver representation** is:

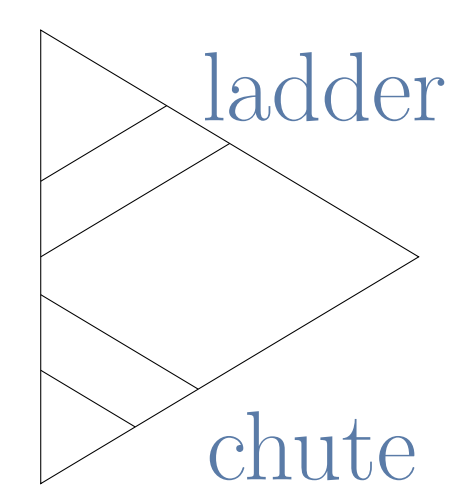

- A finite-dimensional \mathbb{C} -vector space for each vertex.
- A linear map for each arrow.

$$\mathbb{C} \xrightarrow{1} \mathbb{C} \xrightarrow{\begin{pmatrix} 2 \\ 5 \end{pmatrix}} \mathbb{C}^2$$

A **quiver representation variety** $E(\mathbf{w})$ is the space of all quiver representations for a fixed dimension vector \mathbf{w} .

$G(\mathbf{w}) = \mathbf{GL}(w_1) \times \dots \times \mathbf{GL}(w_n)$ acts on $E(\mathbf{w})$ splitting it into orbits.

The set of triangular arrays $\mathbf{P}(\mathbf{w})$

Define the set $\mathbf{P}(\mathbf{w})$ of triangular arrays of nonnegative integers such that:

- $\forall j$, the entries in the j^{th} chute sum to w_j .
- Ladders are weakly decreasing.

Theorem [Achar–Kulkarni–M.]

There is a bijection

$$\{G(\mathbf{w})\text{-orbits in } E(\mathbf{w})\} \xleftrightarrow{1-1} \mathbf{P}(\mathbf{w}) = \{\text{certain tri. arrays}\}.$$

Example of bijection

Theorem (Combinatorial Fourier transform) [Achar–Kulkarni–M.]

There is a bijection

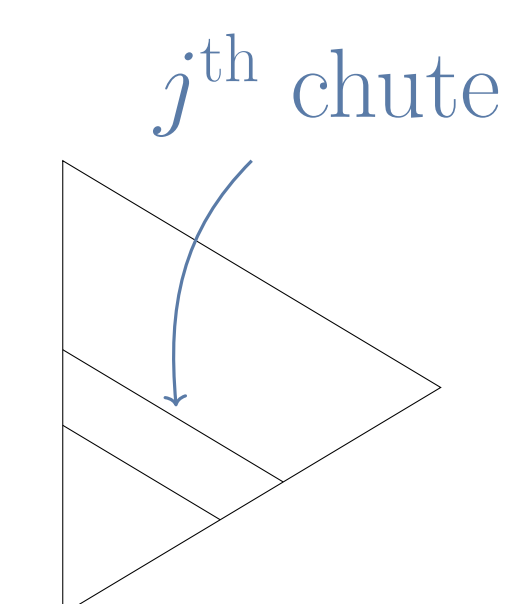

$$\mathbf{P}(\mathbf{w}) \xrightarrow{\mathbb{T}} \mathbf{P}(\mathbf{w}^*)$$

defined inductively by

$$\mathbb{T} \left(\begin{array}{c} Y' \\ \vdots \\ y_{1,n} \end{array} \right) = \tau_n^{y_{1,n}} \tau_{n-1}^{y_{2,n-1} - y_{1,n}} \dots \tau_1^{y_{n,1} - y_{n-1,2}} \left(\begin{array}{c} 0 \dots 0 \\ \vdots \\ \mathbb{T}(Y') \end{array} \right)$$

where $\mathbb{T}(a) = a$.

Definition of τ_j

Define $\tau_j : \mathbf{P}(\mathbf{w}) \rightarrow \mathbf{P}(\mathbf{w} + \mathbf{e}_1 + \dots + \mathbf{e}_j)$ by:

- Add 1 as far down the j^{th} chute as possible, drawing an impassable vertical line there.
- Repeat for chutes $j - 1, \dots, 1$ not crossing lines.

Example of CFT

$$\mathbb{T} \left(\begin{array}{c} 1 \\ \vdots \end{array} \right) = \begin{array}{c} 1 \\ \vdots \end{array}$$

$$\mathbb{T} \left(\begin{array}{c} 1 \\ 0 \\ 0 \end{array} \right) = \begin{array}{c} 0 \\ 1 \\ 0 \end{array}$$

$$\mathbb{T} \left(\begin{array}{c} 1 \\ 0 \\ 2 \end{array} \right) = \tau_2 \tau_1 \left(\begin{array}{c} 0 \\ 0 \\ 1 \end{array} \right) = \begin{array}{c} 2 \\ 0 \\ 1 \end{array}$$

Complete CFT example

Main conjecture (proof in progress)

The bijection \mathbb{T} determines \mathbb{T} on simple perverse sheaves; that is, $\mathbb{T}(\text{IC}(\mathcal{O}_\lambda)) = \text{IC}(\mathcal{O}_{\mathbb{T}(\lambda)})$.
